V8 2000

- \* TCID is a link between the shop floor in the c-shop.
- \* TCID was created in 2002, but functionality is still (now) being changed and added.

~~Ramp~~

~~Ramp~~

Project Goals:-

- Replace TCID to reduce the risks associated with the current situation
- Strive towards common VCC solutions.

TCID is replaced by

- new functionality in SAMS

VO Communication

The new Data PLC

One data PLC for each assembly line section, and one data PLC for all pre-assembly sections

Separate processes in VO and ~~SAS~~ ~~SAS~~ SAMS for each Data PLC

1304:-

Problem Statement :-

TCID (Tracking Controlling and Identification) is used in the TE-Factory for controlling the assembly line and is highly production critical. The system is dependent on a single key resource for maintenance and support

PLC -

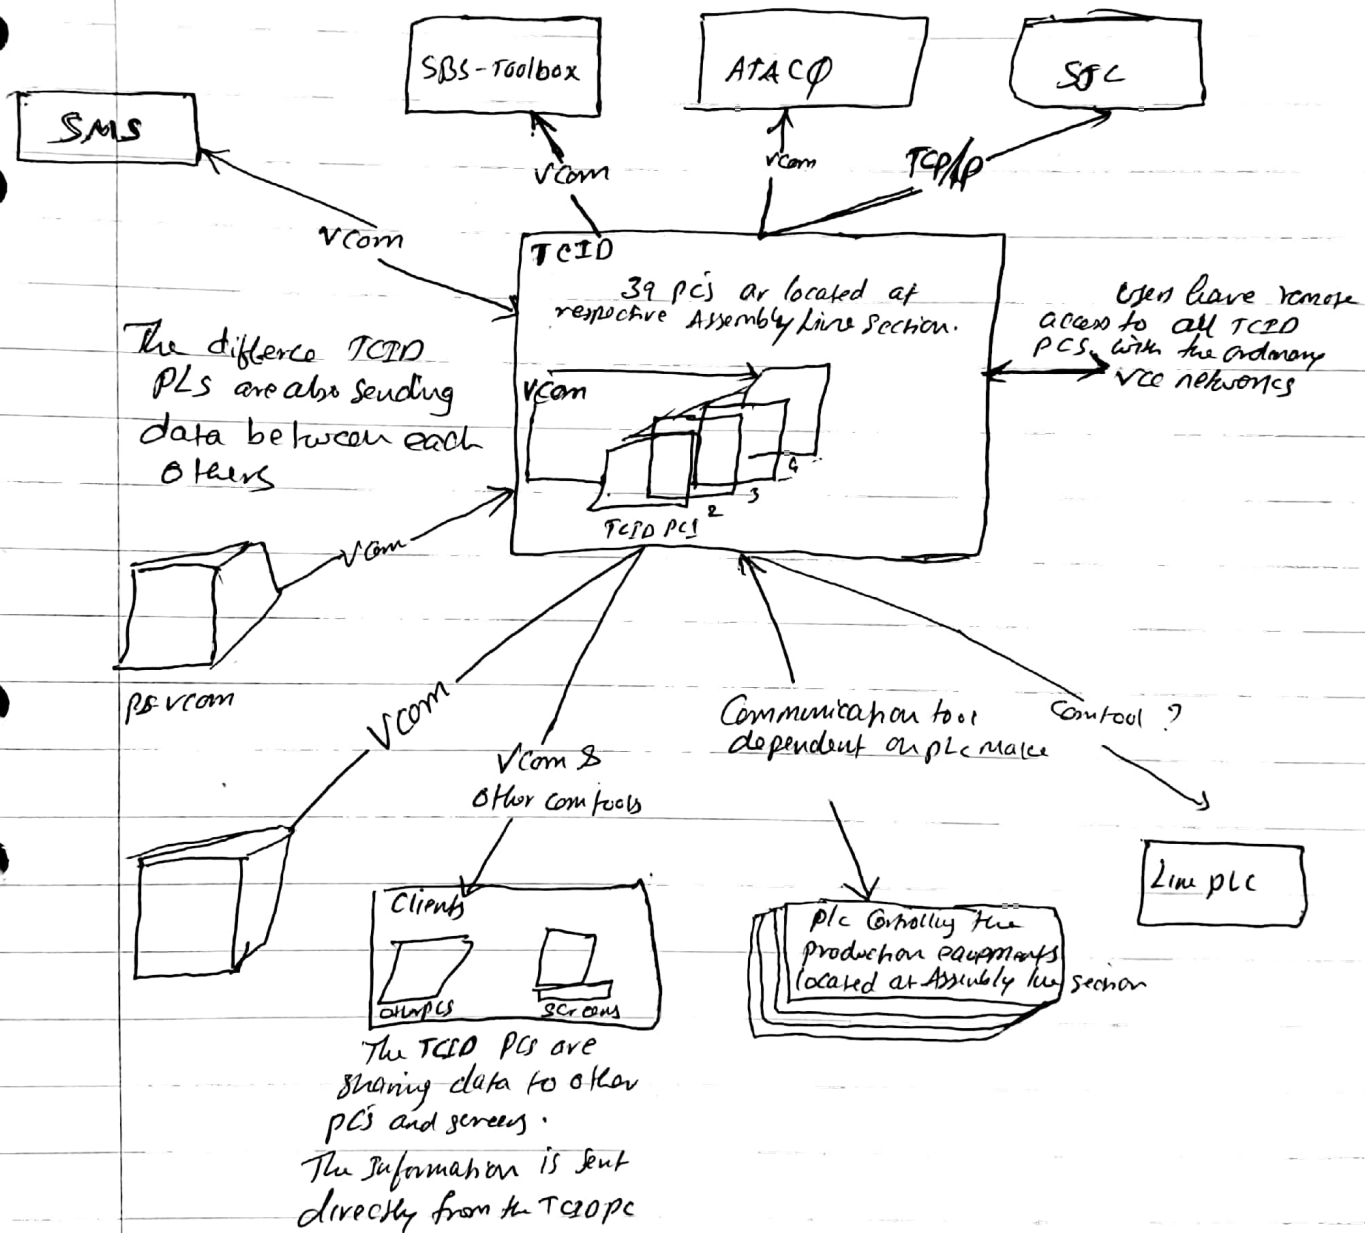

PS-Vcom is an old application that had been used for different purposes to control PLCs in Assembly workshops in Torstanda

Now Application is used for different purposes and may be divided in the main functionalities

~~Poka Yoke~~ ~~purely~~ ~~light~~ ~~every~~ ~~assembly~~

- Transfer location information to SAMS.
- Support to handle operations at Pre Assembly Stations.  
(Poka Yoke & Poka Yoke Andon2)
- Submit triggering information to the SSC server for PLC not controlled by PS-Vcom.

# Current IT Environment for TCID

Torslanda C-factory. Marriage point is where the car body and engine are put together.

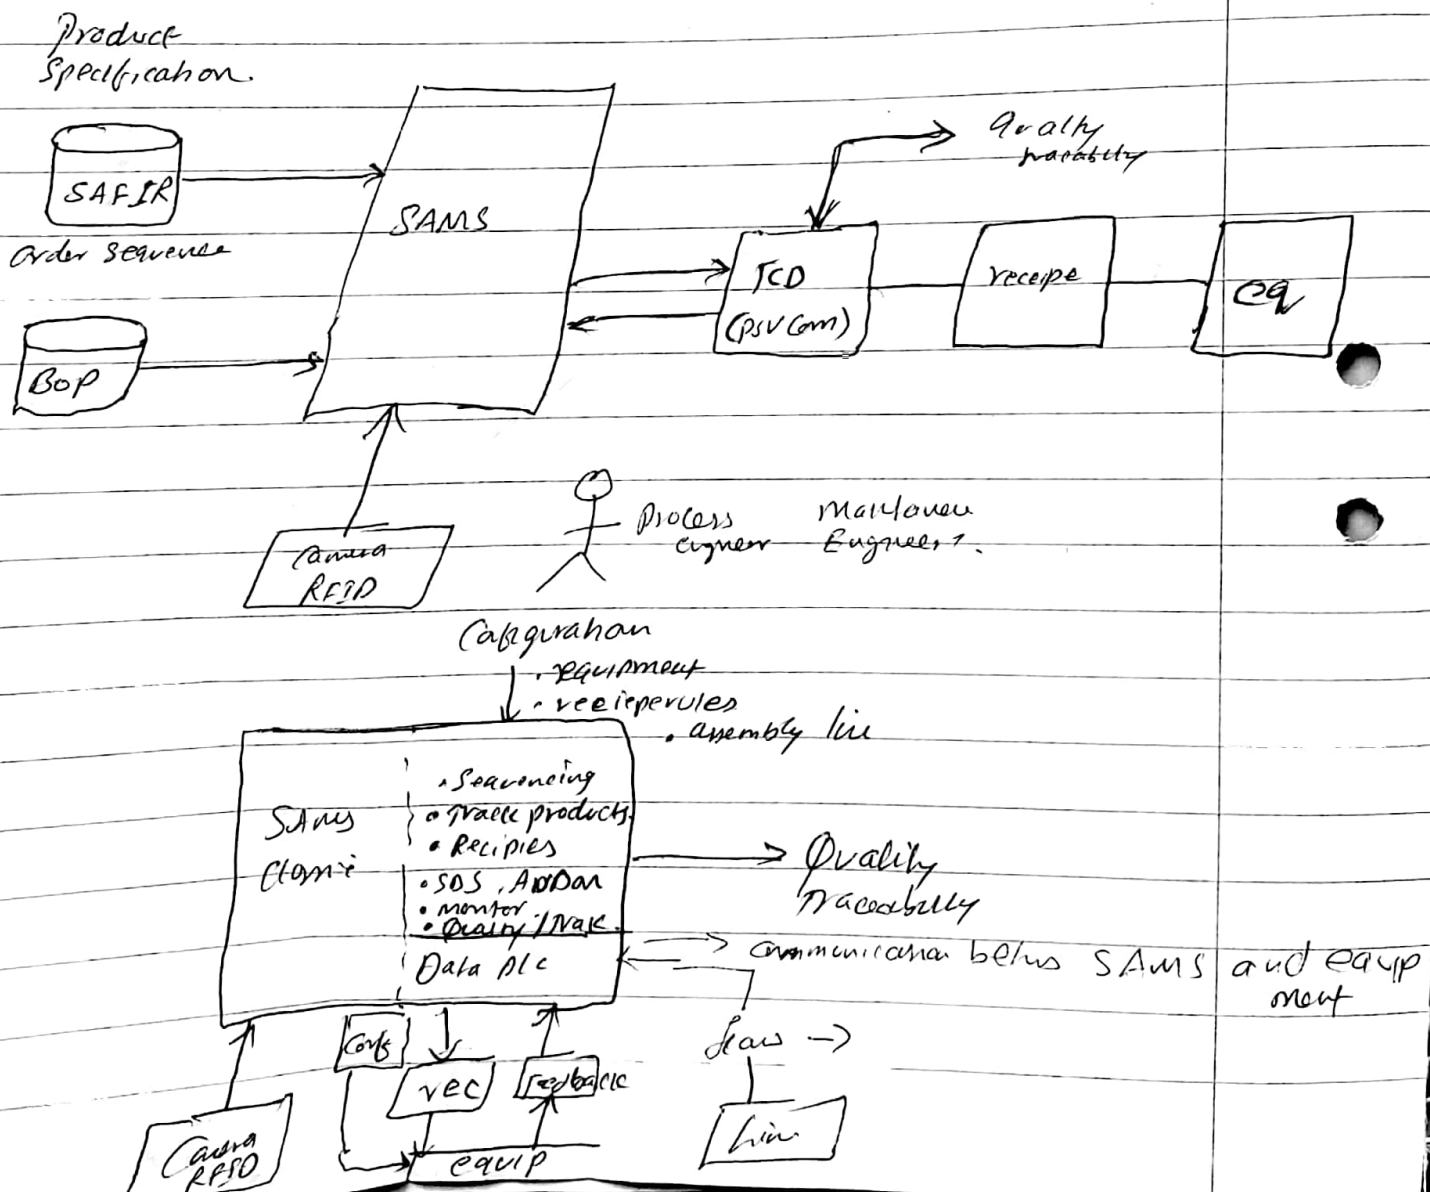

This was implemented and used during 1994 when the 900-series (line1) and the 850-models (line2) was built

A-Shop - body  
B-Shop - painting  
C-Shop - Assembly

Assembly line divided into 39 sections

Each section has → RFID, camera & ladder

→ .

0779/114950

~ 40000  
9250

Assembly line section.

Control poka-yoke → doing right thing for the product  
(Japanese concept)

SBS → Sequence Balancing Systems

3JC → Jener for controlling Screw joints. (one type of carpentry)

## Database - Development

### CIRSS3

### POC System Capacity - Design verified

1. Each line has its own processes in VD and SAMS
2. Each line has its own physical Data PLC
3. The Data PLC is designed for the number of Equipment PLCs per line seen in the diagram, which means we have a future Capacity of approx 4000 p/c in C-shop.

### Design per line

### POC Functional Test

- Request, create and distribute recipes from SAMS to LP202
- Request line info from the line PLC = ✓
- manage inventory in SAMS and update Data PLC
- manage Configuration in SAMS and update LP202

type Sams\_com: Samsbatch - common.com

@ Sams\_com: Samsbatch - common.com

@ Sams\_com: Samsbatch

## Application

SAMSweb → GUI and Backend deployed on websphere.  
Configuration and monitoring of equipment and recipes

SAMSBatch → Background process on open VMS - one instance per Data PLC. Generating and distributing information to the shop floor and collecting results.

VD → Virtual device application for communication between IT and Shop floor - one instance per Data PLC  
- one instance per Data PLC

Data PLC: one PLC per assembly line section with the various stations and equipment

## Application Functional Knowledge:

Communication between SAMS Batch and VD is by VCom.

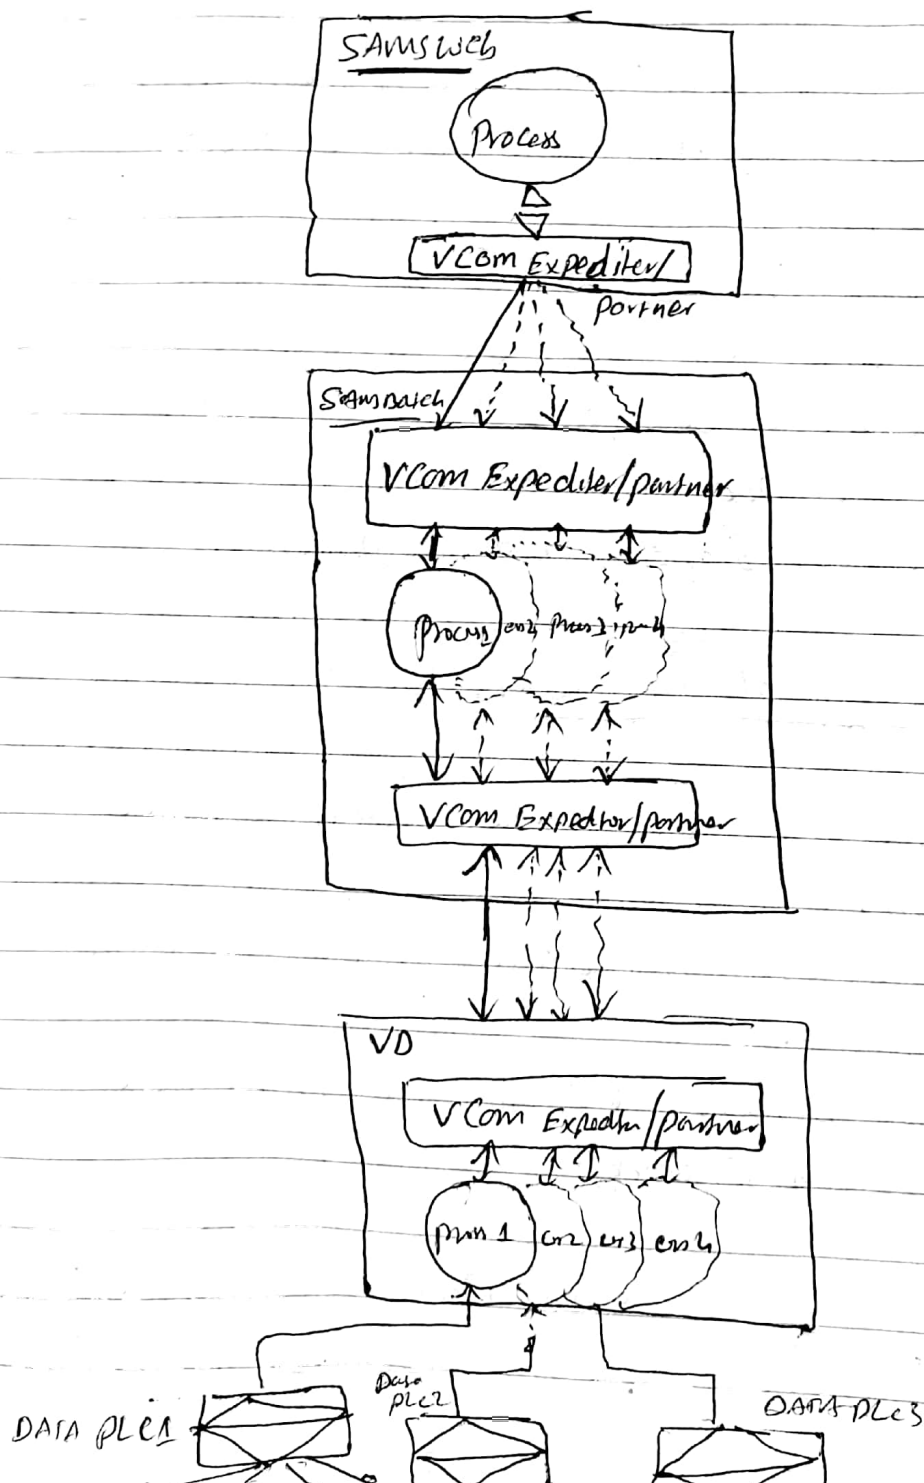

Every process will have its own expediter and partner

Communication between VD and the Data PLC is done by the VDcom protocol.

Communication between SAMSBatch and SAMSweb uses single single partner/expediter pair for

for sending messages to and receiving message from the web application

to send messages to SAMSBatch, SAMSweb uses corresponding Vcom partner for every SAMSBatch instance so that message from VD and from SAMSweb are read from the same queue

# Architecture

## SAMS

It manages location of production objects as they move through the plant together with a local application called TCID (Transaction Control and Identification)

SAMS is responsible for managing the object specific data for each production object through the plant, and communicating this data and other specific information to different systems

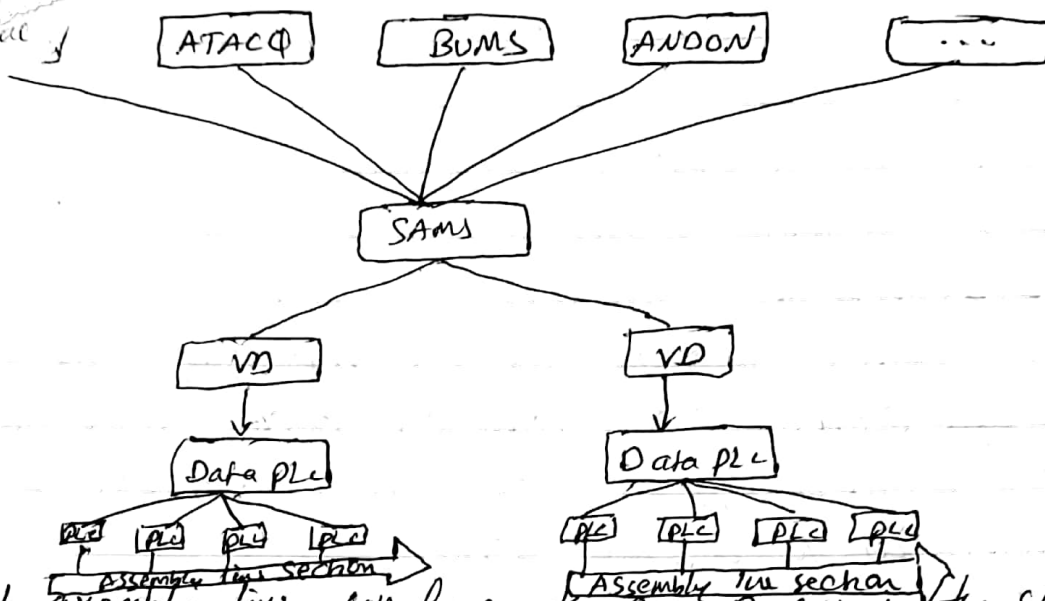

TCID uses this information to create equipment recipes and control codes

## Project Description:

Business objective 1: - Reduce risk for production stop in VCT C-factory

The Business goal to have the TCID Systems replaced, is based on the target to create resilience and significantly reduce the time for assembly line manufacturing interruptions or incidents at VCT

Business objective 2: - Long term cost reduction thru Strategic planning for Common factory System Secure that implemented IT Solution has a direction that makes it possible to use for other factories than VCT

Each assembly line will have its own process in the SAMS System, its own VO processes and its own PLC

This first of all to ensure performance, throughput, response times and high concurrency.

But it also to meant to ensure that the impact of an incident is reduced to one subassembly, and not a larger part of the factory,

The part of middle is covered by the project scope

- Creating proper SAMS processes, and setting up the instances.
- Setting up relevant VO instances
- Creating the PLC software, and setting up the instances. — one for each line and 1 for preassembly

Systems behind SAMS are not to be changed, except for reconfiguration of various system parameters, such as host names, channel names & c.
